MCB-400 Delta T Air Conditioning Monitoring System

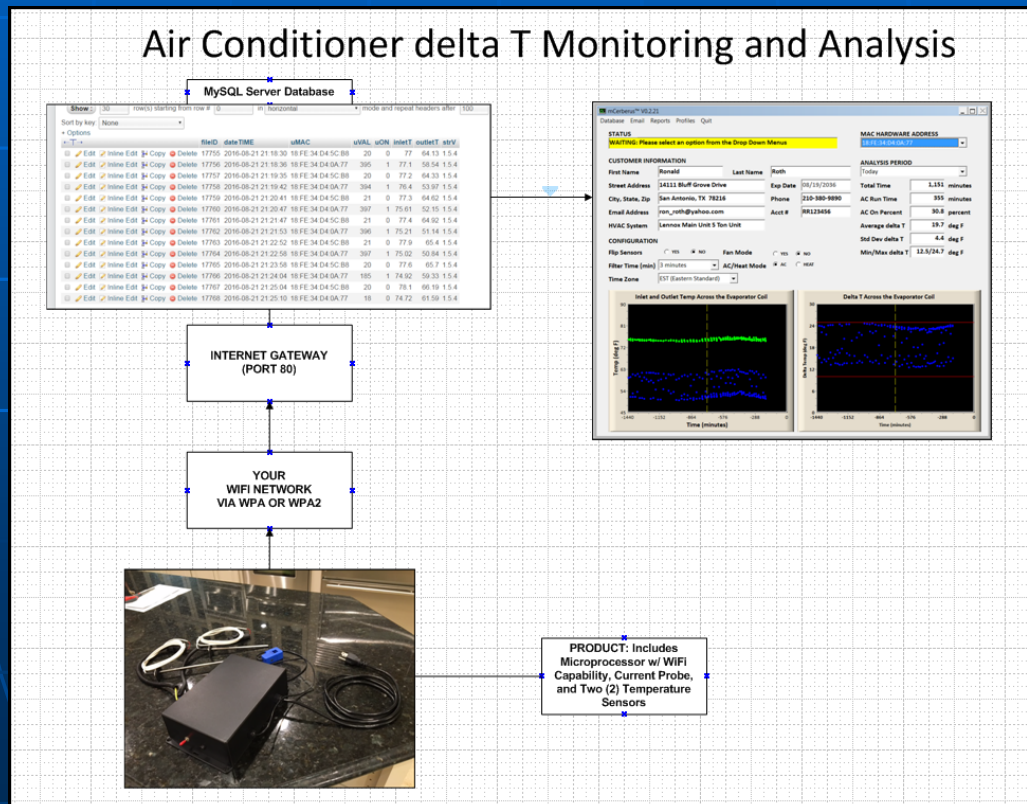

RT Automation  
September 14th, 2016

# Application

- As part of an Air Conditioner install or maintenance check – it is common for the delta T across the evaporator coil to be measured
- The general rule of thumb is that the delta T across the evaporator coil should be 10 to 25 degrees F at steady state
- The product developed is a kit that can be installed on any air conditioning system. It consists of the following:
  - Microprocessor w/ WiFi capabilities
  - Two temperature sensors
  - One current probe (determines if the AC is running or off)
  - MySQL database
- The Product takes measurements every one minute.
- A backend application analyzes the data and determines the current state of the equipment
- Filtering of the data is required in order to determine when the AC is at a “steady state” condition
- If the filtered data “delta T” mean is above or below some established set point – then maintenance of the system is indicated

# Flowchart of Application

- Hardware System records/stores AC data on MySQL Server
- Backend Office Program is used to analyze data

# Installation of Hardware

- Install Inlet Temp Sensor
- Install Outlet Temp Sensor
- Connect AC Current Clamp to Incoming Power to Air Handler
- Connect Power Cord to 120VAC
- Turn ENABLE switch to ON
